Introduction

The Porifera is one among the rare groups of animals on which the biodiversity data have already been documented. In the case of this group, species information and related data are scanty. Therefore universal documentation tools and active communication among taxonomists working in related areas are highly imperative. Computer based biodiversity system has been developed as a universal tool for the documentation of biodiversity data. Linnaeus II software developed by ETI (Expert Centre for Taxonomic Identification) provides a helping hand for the documentation of biodiversity data on sponges[3].

As per the reports of the Zoological survey of India the Indian invertebrate fauna comprises 89,451 species. Some groups of invertebrates have been well documented in the past while others are not. Only very few studies have been made on the taxonomy and biodiversity of rare groups especially the marine sponges. As India is a Signatory to the GATT and Biodiversity Convention (BDC), it is mandatory on our part to study, document and utilize our biodiversity wealth for the betterment of humanity.

Materials and Methods

Four major landing centres were selected during the present study and these were, from north to south, Vizhinjam (Stn. 1), Enayam (Stn.2), Colachel (stn.3) and Kadiyapatnam (Stn. 4) (Map 1). A sample of 100 mussels was collected at random from each centre from different units once or twice every month for a period of one year. The methods suggested by Old[4], Thomas[5], Thomas, et al.[6] Schonberg[7,8] were followed for preparing spicules and for biodiversity studies. The following statistical methods were used in the present study:

Pielou’s D index (D) was the highest at Station I (1.17) and the lowest at station 2 (0.89). Shannon Weaver function[2], H (S), was the highest at Station II (1.85), showing maximum number of species (s = 8), while it was lowest at Station 1 (1.62) with the least number of species (s = 4).

Abstract

A study on the biodiversity indices of boring sponges infesting the brown mussel population of the southwest coast of India was attempted in this paper. Four species, Cliona lobata, Cliona vastifica, Cliona celata and Cliona margaritifera were identified from Station 1, Vizhinjam. From Station II maximum number of species were identified and they are in the order of abundance, Cliona lobata, Cliona vastifica, Cliona celata, Cliona margaritifera, Cliona carpenteri, Thoosa armata, Thoosa hancocki, Aka minuta and Alectona millari. Cliona lobata, Cliona vastifica, Cliona celata and Cliona margaritifera were identified from station III, Colachel and Cliona lobata, Cliona vastifica, Cliona celata, Cliona margaritifera and Cliona carpenteri from Station IV, Kadiyapatnam. Pielou’s D index (D) was the highest at Station I (1.17) and the lowest at station 2 (0.89). Shannon Weaver function[2], H (S), was the highest at Station II (1.85), showing maximum number of species (s = 8), while it was lowest at Station 1 (1.62) with the least number of species (s = 4).

Results and Discussion

The sponge fauna of India is dominated by species of Demospongiae followed by those of hyalospongiae and Calciospongiae. Also 34 species of coral boring sponges have been recorded. The Gulf of Mannar and Palk Bay region has the highest diversity. 319 species followed by Andaman and Nicobar Islands 95 species, Lakshadweep 82 species and Gulf of Kutch 25 species [2]. Values of five diversity indices calculated for each sample are given in Table 1 A & B. Number of species (S) is defined as the total number of species encountered at the station. The number of species at the stations covered ranges from 4 (Station I) to 9 (Station II).

Pielou’s [3] index (D) is concerned with the dominance of species. At the stations covered, it is the highest at Station I (1.17) and the lowest at station 2 (0.89). Species dominance is inversely related to the number of species. The mean (x), standard deviation (Cr) and the coefficient of variation (%) of this index in this study being 1.05, 0.11 and 10.4 correspondingly.

Simpson’s [10] index (Sp) of the degree of concentration or diversity is almost uniform for the Stations I, II and IV (0.999) covered, but it is relatively low at Station III (Sp = 0.996). Mean of this index is 0.998, standard deviation and coefficient of variation being 0.001 and 0.14 respectively.

Margalef’s [9] index (d) varies from 0.63 (Station 1) to 1.12 (Station 2), mean, standard deviation and coefficient of variation being 0.88, 0.1 8 and 19.97 respectively.

Shannon Weaver function [2], H (S), is the highest at Station II (1.85), showing maximum number of species (S = 8), while it is lowest at Station 1 (1.62) with the least number of species (S = 4). Mean (x), standard deviation and coefficient of variation for this index are 1.73, 0.11 and 6.30 respectively.

Heip’s [11] index measures evenness of occurrence of species in a population. In the present study, it varies from 0.77 to 1.35. Low equitability indicates dominance of a few species, while high equitability reflects uniform distribution of species. Mean of this is 1.11, standard deviation and coefficient of variation being 0.23 and 21.05 respectively.

519 species of sponges are known to occur in the Indian seas. Out of that 34 are coral boring have been reported from the Gulf of Mannar [12]. In the present study a total of nine species were identified from five stations along the south west coast of India. In conclusion, this study suggests that species number is the highest number of species and the greatest diversity at Station II (S = 8, H(S) = 1.85 and d = 1.12).
