Abstract:
Obesity is a global health problem in recent years. Adipose tissue was known as a storage tissue increasing with rise of the body mass index the indicator of obesity. The endocrine functions of adipose tissue might contribute to obesity, diabetes mellitus, cancer and infertility. Many environmental chemicals affect actions of hormones so these chemicals have been defined as endocrine-disrupting chemicals(EDCs) or endocrine disruptors. With the increase in production of EDCs in the world parallels the global obesity prevalence increases. The reported rise in obesity of children under 2 years of age is also suggestive of alterations during development. In early life EDCs exposure can influence epigenetic programming of obesity. These pollutants can pass from mother to fetus via placenta and breast feeding. Some obesogens are found in nature such as phytoestrogens and the others are mostly synthetic chemicals. These chemicals commonly found in pesticides /herbicides, industrial and household products, plastics detergents and personal care products. These substances are defined persistant organic pollutant (POPs) and they accumulate in adipose tissue. We searched current literature with the key words: obesogens, POPs, endocrine disruptors in pubmed and filtered the results with articles in recent 5 years. This mini reviewprovides current experience about association between obesity and endocrine disrupting chemicals.

Keywords: Obesity; Endocrin disrupting chemicals; Environmental pollutants

Introduction
Obesity is a global health problem in recent years[1,2]. Adipose tissue was known as a fat storage tissue increasing with the rise of the body mass index the indicator of obesity. Recently it is well known that adipose tissue is not only a storage tissue but also has endocrine and metabolic functions[3]. The major body weight regulators and inflammatory agents such as leptin, peroxisome proliferator-activated receptors (PPARs) is controlled by adipose tissue. These regulators stimulate food intake, metabolic efficiency, and energy storage[4-5].

The endocrine functions of adipose tissue might contribute to obesity, diabetes mellitus, cancer and infertility[6]. Many environmental chemicals affect actions of hormones so these chemicals have been defined as endocrine-disrupting chemicals(EDCs) or endocrine disruptors[1,7]. With the increase in production of EDCs in the world parallels the global obesity prevalence increases[8,9]. Obesogens as xenobiotic chemicals which bring about decreasing detoxification mechanism of body can alter the normal progress of adipogenesis or energy balance[3,8,10,11]. Some obesogens are found in nature such as phytoestrogens and the others are mostly synthetic chemicals. These chemicals commonly found in pesticides/herbicides, industrial and household products, plastics detergents and personal care products[1,7]. These synthetic chemicals are enduring so they do not degrade in the nature. For this reason these substances are defined persistant organic pollutant (POPs) and they accumulate in adipose tissue. Common EDSs are Tributyltin (TBT), 4-Nonylphenol used in industry, persistent organochlorines (POPs) used in agriculture industry, diethylstilboestrol (DES) as a pharmaceutical, bisphenol A (BPA) and phthalates used in plastics, parabens as preservatives, phytoestrogens in edible plants, polybrominated diphenylethers (PBDEs) as flame retardants. We searched current literature with the key words: obesogens, POPs, endocrine disruptors in pubmed and filtered the results with articles in recent 5 years. This mini reviewprovides current experience about association between obesity and endocrine disrupting chemicals.

used in plastics, parabens as preservatives, phytoestrogens in edible plants, polybrominated diphenylethers (PBDEs) as flame retardants[1]. Tributyltin (TBT) used as a biocide in antifouling paints applied to the hulls of ships and cause imposex in molluscs and to masculines female fish[15]. TBT may inhibit aromatase which is responsible for the conversion of testosteron into estrogens[16,17]. 4-Nonylphenol is has eustrogenic effects and used as asurfactant in industry and domestic applications[18,19]. POPs are used mostly as insecticides (DDT, DDE), Diethylstilbestrol (DES) is a non steroidal estrogen. The DES toxicity is interferences with reproductive system and association with female reproductive tract cancers[20]. Bisphenol A a component of polycarbonat plastics and resins. It is ubiquitous in food and beverage containers, baby bottles, toys, dental sealants. Foods and beverage can be contaminated by BPA as a result of heating or acidic/basic condition during storage[8]. Phythalates are diester of phthalic acid. They are used in commonly plastic such as polyvinyl chloride and some products such as food and beverage packaging, soaps, shampoos, cosmetics and hair sprays[8]. Parabens are mostly found in personal care products, foods, pharmaceutical products and paper products[21]. Phytoestrogens are found naturally in plant such as soy and soy products. They are defined dietary estrogens. Increased consumption of soy products and soy supplements cause exposure to phytoestrogen. Genstein which is predominant isoflavon in soybean is responsible of changes in the metabolic and adipogenic regulators such as PPAR gamma[22]. Recent experimental data supported that genistein dysregulates the body composition, in a dose-dependent and gender-specific manner, disrupting and reprogramming the signals dictating adipose tissue expansion, likely throughout the early-life epigenetic regulation of Wnt10b, a further key adipogenic gene in adipose tissue[23]. Polychlorinated Bisphenols are organic chemicals and found in electricam equipment. Some PBCs are identified as EDCs because of their estrogenic and antiandrogenic effects[8,25]. Although PCBs were banned at the end of the 1970s in many countries because of environmental toxicity, these compounds still remain present in the environment due to their high stability and represent one of the key constituents of POPs all over the world[8,26]. Perfluoralkyl substances are non organochlorine POPs used in industrial applications. PFASs are detectable in human blood[8].

Pesticides consumption is the most important source of EDCs exposure[24,27]. Two main types of pesticides are organochlorine and organophosphate pesticides. Although Organochlorine pesticides was banned, they are still detected in tap water. Organophosphate pesticides have replaced organochlorine[27]. These pesticides enter into food chain and tends to persist in environment and accumulate human body[8,28]. Human body might exposure to these chemicals with oral intake by contaminated water and food consumption, respiration, or dermal absorption[1,7]. EDCs related obesity may involve in several mechanisms. EDCs disrupt lipid and glucose metabolism (endocrine regulated metabolic process) and also neuroendocrine control of appetite and satiety[1,8,16,29,30]. Moreover, EDCs affect pro inflammatory mechanisms by activating oxidative stress sensitive transcription factors such as nuclear factor kappa B (NFkB) stimulating cytokines, chemokines and adhesion molecules in the vascular endothelium. Along the pro inflammatory mechanisms, EDCs are associated with an increased risk of non communicable or chronic diseases such as cardiovascular diseases or diabetes and insulin resistance[1,16,31,32]. As EDCs are accumulated in fat tissue several studies shown an increasing in blood POPs following fat loss when obese individuals lose weight with diet or bariatric surgery, with approximately 30 kg decrease in fat mass[33,34].

Gender, dose, life stage and duration of EDCs exposure is important[35]. In obesogen hypothesis, EDCs effect obesity related epigenetic variations and microbiota profile. EDCs stimulate expression of noncoding RNAs, changes in chromatin structure and DNA and histone methylation. Low levels of DNA methylation can produce active adipogenic genes so adipocyte number increases. Increasing active adipogenic genes may change metabolic set point[8,35]. According to set point theory, body weight sustains stable from internal regulatory mechanisms that are genetically determined[36]. Change in metabolic set point causes weight regain after weight loss[8,35].

In 14th week of gestation, adipogenesis begins[37,38] and goes on during postnatal period[38,39]. The reported rise in obesity of children under 2 years of age is also suggestive of alterations during development[39,40]. Studies shown that babies born to mother who smoked tobacco during pregnancy have been found to have a low birth weight but later these babies are at increased risk of obesity[41]. Other study of children in the Faroe Island shown that prenatal exposure to polychlorinated bisphenols and dikloro difenil dikloroetenil in seafood is related with increased body weight[1,42]. In early life EDCs exposure can influence epigenetic programming of obesity[42]. These pollutants can pass from mother to fetus via placenta and breast feeding[43].

In a cohort conducted in 189 adult obese individuals aimed evaluation of POPs level in visceral and subcutaneous adipose tissue has found that both were affected with POPs but visceral adipose tissue was more sensitive to accumulation. Additionally they found a relationship between increased POPs accumulation and increased metabolic risk as dysglycemia and high blood pressure had positive relationship with elevated POPs level[44].

A rodent model experiment female mice were fed with high fat and high sucrose diet with or without pollutants. The pollutants were prepared as a mixture of low doses. It contained ‘Tolerable Daily Intake (TDI)’ doses of tetrachlorodibenzo-p-dioxin, PCB, bisphenol A and phthalate. Each pollutant was used at a dose grossly corresponding to the TDI reference dose. They found that mice fed with pollutants even at TDI doses had increased body weight, plasma fasting glucose and plasma insulin levels. Additionally found out that metabolic aoutcomes were sex and age depended that female were more sensitive to exposure in different stages of life span[42].

One of the main issues of the world is obesity which is related to genetic and environmental factors. Although obesity is related with excessive food consumption or lack of exercise with the increasing industrialization it is also associated with strongly environmental factors such as synthetic chemicals and pollutants. These substances accumulate adipose tissue and mimic endocrine hormones. The early exposure to EDCs in prenatal and postnatal period which is especially before 2 years of life increases risk for adulthood obesity. When considering the relationship between obesity and EDCs, production of EDCs must be controlled by policies and exposure to these substances especially early life stages should be reduced.
**Abbreviations:** PPARs: Peroxisome Proliferator Activated Receptors; EDCs: Endocrine Disrupting Chemicals; POPs: Persistent Organic Pollutant; TBT: Tributyltin; DES: Diethylstilbestrol; BPA: Bisphenol A; PBDEs: Polybrominated Diphenyl-ethers; DDT: Dikloro Difenil Trikloroethan; DDE: Dikloro Difenil Dikloroetilen
